1 Network Structure

We provide structure details of the visual encoder, the inertial encoder, the policy network, and the pose estimation network in Table 1, 2, 3, and 4 respectively. The batch size and sequence length are denoted by $B$ and $T$. For the visual encoder, we adopt the FlowNetS structure proposed in [2], which is trained on the FlyingChairs dataset [2] for optical flow estimation. We adopt the pre-trained checkpoint ‘flownets_bn_EPE2.459.pth.tar’ from https://github.com/ClementPinard/FlowNetPytorch as our initialization.

2 Additional Data Processing and Training Details

The KITTI Odometry dataset does not come with IMU data. Thus, we extract the IMU data from the KITTI raw dataset and associate them with the KITTI Odometry dataset as shown in Table 5. The IMU data and image frames are not synchronized. Therefore, we apply linear interpolation to the raw IMU data to obtain data synchronized to the image time index. The training sub-sequences are extracted from the original long sequences with an overlap of 1 frame between sub-sequences. During training, we apply horizontal flipping to images with 50% probability and adjust the ground truth poses and IMU data accordingly. A weight decay of $5 \times 10^{-6}$ is applied to the visual encoder, inertial encoder, and the pose network training to avoid overfitting.

3 FLOPS Computation

We list the FLOPS counting formula for each type of layers in Table 6. The total number of FLOPS of each individual network is shown in Table 7 where computations of non-linear activation functions are ignored. It is observed the visual encoder exhibits a $3700 \times$ higher FLOPS than that of the inertial encoder. The total number of FLOPS of a test sequence is calculated using multiple sampled policies and is then averaged over the total time (in seconds).

Table 6: FLOPS counting for each layer type.

4 Complete Results for KITTI

In this section, we show the complete results for all KITTI test sequences (Sequence 05, 07, and 10) in Table 8, 9, and 10. For stochastic methods, we show both the mean and standard deviation.

5 Additional Qualitative Analysis on KITTI

We present additional visualizations of test paths. Figure 1 shows the full-modality baseline, two sub-optimal strategies (random sampling and regular
skipping), and our proposed method on Sequence 10. Figure 2 - 6 contain the visual interpretation of our method on Sequence 05 and 10 with $\lambda = 5 \times 10^{-5}$, and Sequence 05, 07, and 10 with $\lambda = 3 \times 10^{-5}$. The visualization on Sequence 07 with $\lambda = 5 \times 10^{-5}$ is shown in the paper.

6 Test Results on EuRoC

We present the results of our method tested on the EuRoC dataset [1] for indoor scenarios. The EuRoC dataset contains 11 tightly-synchronized stereo videos and IMU measurements collected by an Asctec Firefly hex-rotor helicopter. The ground truth poses are collected by a Leica MS50 laser tracker or Vicon 6D motion capture system. We select the sequence MH.04.2 difficult for testing and use the remaining sequences for training. The images and IMU data are sampled at 20Hz and 200Hz respectively. We use the monocular images from camera 1 of the EuRoC dataset. The system parameters and training procedure are the same as those used for KITTI, except for $\alpha$ which is set to 10 for EuRoC. Table 11 shows the results of the full-modality baseline and our proposed method with different $\lambda$. Similar with KITTI, disabling the visual modality does not lead to significant performance degradation. It is observed that the best translational RMSE is achieved with $\lambda = 1 \times 10^{-6}$ and the best rotational RMSE with $\lambda = 3 \times 10^{-6}$.
